[About this patent](#)[Read this patent](#)**Replication method** Yoko Hirashima et al[Read this patent](#)[Download PDF](#)[View patent at USPTO](#)[Abstract](#) | [Drawing](#) | [Description](#) | [Claims](#)**Abstract**

A directory system for performing replication of directory data, in which a directory server on the consumer side can reconstruct replica data using a backup kept at any point in time. Information 10c for specifying the entry changed for the last time by replication performed by replication service 10' is recorded into the replica data 9c managed by the directory server on the consumer side. Based on this information, the replication service 10' can know the entry on which next replication is to be performed. Thus, the replication service 10' can recognize the difference between the master data 9s managed by the directory server on the supplier side and the replica data 9c, and can perform replication on this difference when only the replica data 9c is reconstructed using the backup.

Patent number: 6301589**Filing date:** Dec 2, 1998**Issue date:** Oct 9, 2001**Inventors:** Yoko Hirashima, Satoshi

Kikuchi, Hitoshi Yui

Assignee: Hitachi, Ltd.**Primary Examiner:**

Jacques Veillard

U.S. Classification707/204; 707/8; 707/104;707/200; 907/200;907/201; 907/223; 379/34**Claims**

What is claimed is:

1. A replication method for keeping contents of master data and contents of replica data identical to each other in a directory system, in which, a first directory server manages the master data of directory data and records and holds replication log of operations in changing said master data; one or more second directory servers each manages its replica data as a replica of said master data; and said first directory server and said one or more second directory servers are capable of being connected through a network; wherein said replication method comprises: said first directory server acquires a replication log which becomes an object of processing out of the replication log recorded and held by said first directory server, and issues a replication request that requests performing, on said replica data, the same operations as operations corresponding to the acquired replication log to said second directory server;

said first directory server and the second directory server record an identifying information for specifying the replication log corresponding to said operations performed by said second directory server when said operation performed in accordance with said replication request is successful; and the identifying information recorded by said second directory server is referred to, so as to decide the replication log to be acquired, in acquiring the replication log which is to be a new object of processing from the replication log recorded and held by said first directory server.

2. The replication method according to claim 1, wherein said replication server issues a directory access request that requests performing an operation of searching said identifying information, to said second directory server, so as to refer to the identifying information recorded in the replica data managed by said second directory server.

3. The replication method according to claim 2, wherein: said replication server issues a directory access request that requests performing an operation of recording said identifying information, to said second directory server, so as to record said identifying information into the replica data managed by said second directory server.
